Task 4:

Reflection:

The fine tuning made it much easier to accurately detect the correct digit on the first try. I think one main reason is because the model was specialized to recognize the way I draw values. This is supported by the fact that the largest improvement of digit recognition (qualitative observation) was in digits that can be drawn multiple ways like 4, 5, or 8.

Without fine tuning they didn't have my "handwriting" signature embedded into the model for example how I draw 8 as a figure eight shape rather than two circles. I also got more confident after the fine tune. Even if the other model got one on the first try it usually was less confident than the fine tuned model which was consistently on the upper level of confidence scale.
